Equazioni differenziali di primo grado

▣ **Esercizio 1.1.1.** Si determini la soluzione $y(t)$ del seguente problema di Cauchy

$$\begin{cases} y' = \frac{y^2}{y^2 + 4} t \\ y(0) = 2 \end{cases}$$

Inoltre si determini il valore $\alpha > 0$ per cui $\frac{y(t)}{t^\alpha}$ tende a un numero finito e non nullo per $t \rightarrow +\infty$.

$$\frac{y^2 + 4}{y^2} \cdot y' = t$$

$$\int \frac{y^2 + 4}{y^2} \cdot y' dt = \int t dt + C$$

$$u = y$$

$$du = y' dt$$

$$\downarrow u = y$$

$$\int \frac{y^2 + 4}{y^2} dy = \frac{t^2}{2} + C$$

$$\int 1 dy + 4 \int y^{-2} dy = \frac{t^2}{2} + C$$

$$y - \frac{4}{y} = \frac{t^2}{2} + C$$

$$\frac{y^2 - 4}{y} = \frac{t^2}{2} + C$$

$$y(0) = 2$$

$$\downarrow$$

$$\frac{2^2 - 4}{2} = \frac{0}{2} + C$$

$$\frac{0}{2} = C$$

$$C = 0 \rightarrow$$

$$\frac{y^2 - 4}{y} = \frac{t^2}{2} \rightarrow$$

$$\frac{y^2 - 4 - \frac{t^2 y}{2}}{y} = 0$$

$$y(t) = \frac{\frac{t^2}{2} \pm \sqrt{\frac{t^4}{4} + 16}}{2} = \frac{t^2 \pm \sqrt{t^4 + 64}}{4}$$

$$\downarrow$$

$$y(0) = 2$$

$$\downarrow$$

$$\frac{0^2 \pm \sqrt{64}}{4} = \begin{cases} +2 \\ -2 \end{cases} \quad (\text{Non accettabile}) \rightarrow y(0) = 2$$

Soluzione 1:

$$y(t) = \frac{t^2 + \sqrt{t^4 + 64}}{4}$$

$$\lim_{t \rightarrow +\infty} \frac{y(t)}{t^\alpha} = \frac{t^2 + \sqrt{t^4 + 64}}{4 t^\alpha} = \lim_{t \rightarrow +\infty} \frac{t^2 + t^2 \sqrt{1 + \frac{64}{t^4}}}{4 t^\alpha} =$$

$$= \lim_{t \rightarrow +\infty} \frac{x t^2}{4 t^\alpha} = \lim_{t \rightarrow +\infty} \frac{t^2}{2 t^\alpha}$$

$1 + \frac{64}{+\infty} = 1$

L'unico modo per avere un numero finito è che il grado del numeratore e del denominatore sia uguale, quindi:

$$\alpha = 2 \rightarrow \lim_{t \rightarrow +\infty} \frac{t^2}{2 t^2} = \lim_{t \rightarrow +\infty} \frac{1}{2} = \frac{1}{2}$$

▮ **Esercizio 1.1.2.** Si determini la soluzione $y(t)$ del seguente problema di Cauchy

$$y' \cdot (2e^{2y} + 6e^y) = t^2 + t$$

$$\int y' \cdot (2e^{2y} + 6e^y) dt = \int t^2 + t dt + C$$

$$u = y$$

$$\downarrow u = y' dt$$

$$\downarrow u = y$$

$$2 \int e^{2y} dy + 6 \int e^y dy = \frac{t^3}{3} + \frac{t^2}{2} + C$$

$$2 \cdot \frac{e^{2y}}{2} + 6 e^y = \frac{t^3}{3} + \frac{t^2}{2} + C$$

$$e^y = -3 \pm \sqrt{\frac{t^3}{3} + \frac{t^2}{2} + 16}$$

$$y(0) = 0$$

$$e^0 = -3 \pm \sqrt{\frac{0}{3} + \frac{0}{2} + 16} = -3 \pm \sqrt{16} = -3 \pm 4 = \begin{cases} -7 & \text{non accettabile} \\ 1 \end{cases}$$
